# 1 Introduction

## 1.1 Motivation

Graph theory is a fundamental field of mathematics with significant relevance in computer science due to its ability to model relationships between objects. One of the key challenges in computer science is graph traversal and exploration, which involves systematically navigating through the nodes of a graph with a specific purpose. This topic has practical applications across diverse fields, such as network routing, robotics, procedural generation, electronics design, and more.

When considering the complexities and time constraints imposed by real-world environments, graph exploration must be expanded to consider multi-agent systems. In such systems, multiple autonomous agents collaborate to explore graphs, aiming to distribute tasks to achieve optimal efficiency. However, one of the challenges in these type of system is communication, as strategies need to balance the trade-off between the amount of information shared among agents and the cost of sharing it.

Various versions of this problem have been explored in research. One such approach, discussed by Kivelevitch and Cohen (2010), proposed a generalization of Tarry’s Algorithm with significant emphasis on minimizing data transfer. Nevertheless, this solution is limited to mazes and does not extend to general graphs.

Despite the previously mentioned research, the concept of zero-communication exploration has not been concretely established in the literature. We believe this gap is significant, as practical situations might involve scenarios where communication is limited or impossible due to bandwidth limitations or energy consumption, such as deep-sea exploration, search with energy-limited agents, or high-efficiency state space search.

This work aims to address this gap by presenting a continuation and expansion of a method initially developed for perfect maze exploration (NAEEM, 2021) as discussed by Rodrigues (2024). Building upon this groundwork, the research extends the method to accommodate diverse graph structures by removing dependencies on specific projects. General improvements, such as structuring the exploration into well-defined and extensible

classes and incorporating built-in testing, strive to make the development process more versatile and robust, paving the way for broader applications in multi-agent systems.

## 1.2 Objective

This study aims to propose a viable algorithm for graph exploration by multi-agents, specifically targeting the identification of a goal node. A previous paper by Rodrigues (2024) discussed an approach for perfect maze exploration, which can be modeled as a tree, a connected acyclic undirected graph. Expanding the proposed algorithm to connected cyclic graphs could allow further discussion and contribute to research in real-world applications such as robotics, as well as in the theoretical analysis of parallelism and communication between agents.

## 1.3 Definitions

This section aims to define key concepts in graph theory and multi-agent exploration that are essential for understanding the context and methodology of our research, ensuring clarity and consistency in the subsequent discussions.

### 1.3.1 Graph

Graphs are structures in mathematics and computer science used to represent relationships between pairs of objects. According to Manber (1989), a graph  $G = (V, E)$  is defined as a set  $V$  of vertices (or nodes) and a set  $E$  of edges, that connect pairs of vertices.

#### 1.3.1.1 Common Nomenclature

In graph theory, the basic terminology includes the following components:

- **Vertex (Node):** The fundamental unit of a graph, representing an object or a point.
- **Edge:** A connection between a pair of vertices, representing a relationship between them.
- **Adjacency:** Two vertices  $v$  and  $w$  of a graph  $G$  are adjacent if there is an edge  $vw$  joining them, and the vertices  $v$  and  $w$  are then incident with such an edge. (WILSON, 1996)

- Degree: Degree of a vertex  $v$  of  $G$  is the number of edges incident with  $v$ . (WILSON, 1996)
- Path: A path in a graph  $G$ , as defined by Wilson (1996), is a finite sequence of edges of the form  $v_0v_1, v_1v_2, \dots$  in which any two consecutive edges are adjacent, all edges are distinct and all vertices  $v_0, v_1, \dots, v_m$  are distinct (except, possibly,  $v_0 = v_m$ ).
- Cycle: A path where  $v_0 = v_m$  and with at least one edge. (WILSON, 1996)

### 1.3.1.2 Key Properties

A few key properties of graphs that interest us are:

- Connectivity: A graph is connected if and only if there is a path between each pair of vertices. (WILSON, 1996)
- Acyclicity: A graph is acyclic if it has no cycles. A tree is a special case of an acyclic connected graph.

### 1.3.1.3 Traversal

Graph traversal is the process of visiting all the vertices in a graph in a systematic manner. Two fundamental algorithms for graph traversal are:

- Breadth-first search (BFS): Expands the frontier between discovered and undiscovered vertices uniformly across the breadth of the frontier. (MANBER, 1989)
- Depth-first search (DFS): Explores edges out of the most recently discovered vertex  $v$  that still has unexplored edges leaving it. (MANBER, 1989)

## 1.3.2 Agent

An agent in maze exploration, as defined by Kivelevitch and Cohen (2010), is an entity able to move within the maze in any direction as long as it does not encounter obstacles.

In the context of graph exploration, this concept extends to an agent's ability to traverse edges between vertices within the graph structure. Each agent acts independently, making decisions based on its individual memory and the local information available at its current vertex and its adjacent edges.

### 1.3.3 Mixed Radix

A mixed radix system is a positional numerical system in which the numerical base for each digit varies. This allows for more flexible representation of numbers, accommodating various scales within the same numerical framework.

One mathematical approach for representing mixed radix numbers can be found in Arndt (2011), which establishes a comprehensive arithmetical method for manipulating them. However, for the specific subset of real numbers within the interval  $[0, 1]$ , a more specialized approach is utilized, as described by Rodrigues (2024).

In this context, the mixed radix representation  $A = [a_0, a_1, a_2, \dots, a_{n-1}]$  of a number  $x$  with respect to a radix vector  $M = [m_0, m_1, m_2, \dots, m_{n-1}]$ , where  $x \in [0, 1]$ , is given by:

$$x = \sum_{k=0}^{n-1} a_k \prod_{j=0}^k \frac{1}{m_j} \quad (1.1)$$

where  $0 \leq a_j < m_j$ . (RODRIGUES, 2024)

For instance, if  $x$  is represented by  $2_31_21_40_31_5$ , and considering that  $a_i$  is on the left of  $a_{i+1}$ ,  $x$  might be transformed to the decimal base by the following steps:

$$x = 2_31_21_40_31_5 \quad (1.2)$$

$$A = [2, 1, 1, 0, 1] \quad (1.3)$$

$$M = [3, 2, 4, 3, 5] \quad (1.4)$$

$$n = 5 \quad (1.5)$$

$$x = \sum_{k=0}^4 a_k \prod_{j=0}^k \frac{1}{m_j} \approx 0.8777778 \quad (1.6)$$
